

Accident Insights: Exploring the Potential and Challenges of Storing Accident Data in SQL Relational Database

Introduction

- ❖ Road traffic accidents continue to be a major cause of injuries and fatalities, thus becoming an urgent concern for people all over the world (Gururaj., 2008). Governments and organisations work to reduce these risks through a variety of strategies, such as collecting accident data, better infrastructure, stronger traffic laws, and public awareness programmes (WHO., 2015)
- ❖ The accident database contains information about accidents in the UK
- ❖ The database contains 4 tables namely Accident, Casualty, Vehicle and LSOA
- ❖ The aim of this project is to showcase the power of data analysis and the role of a data scientist in leveraging an SQL relational database to gain valuable insights from the accident database

Technical Issues of Storing Data

▼
01

Data Security and Privacy Breaches: Personal data in the AccidentDB, such as names and other identifiable information, needs to be protected.

▼
02

Data Integrity: Maintaining data integrity is crucial to ensure the accuracy and reliability of the information stored in the AccidentDB.

▶ 03

Scalability: As the AccidentDB grows and more data is added, scalability becomes important to handle increased storage requirements, user concurrency, and performance demands.

Ethical Issues of Storing Data

▶ 01

Informed Consent: Obtaining informed consent from individuals is crucial.

▶ 02

Purpose limitation in relation to the data collected: AccidentDb should only Contain data relevant to its purpose.

Legal Issues of Storing Data

01

Regulations Compliance : Organizations must comply with relevant data protection laws and regulations

02

Data Retention Policies: Establishing appropriate data retention policies is crucial.

03

Consent and Individual Rights: Organizations must obtain appropriate consent from individuals for the collection, processing, and storage of their personal data.

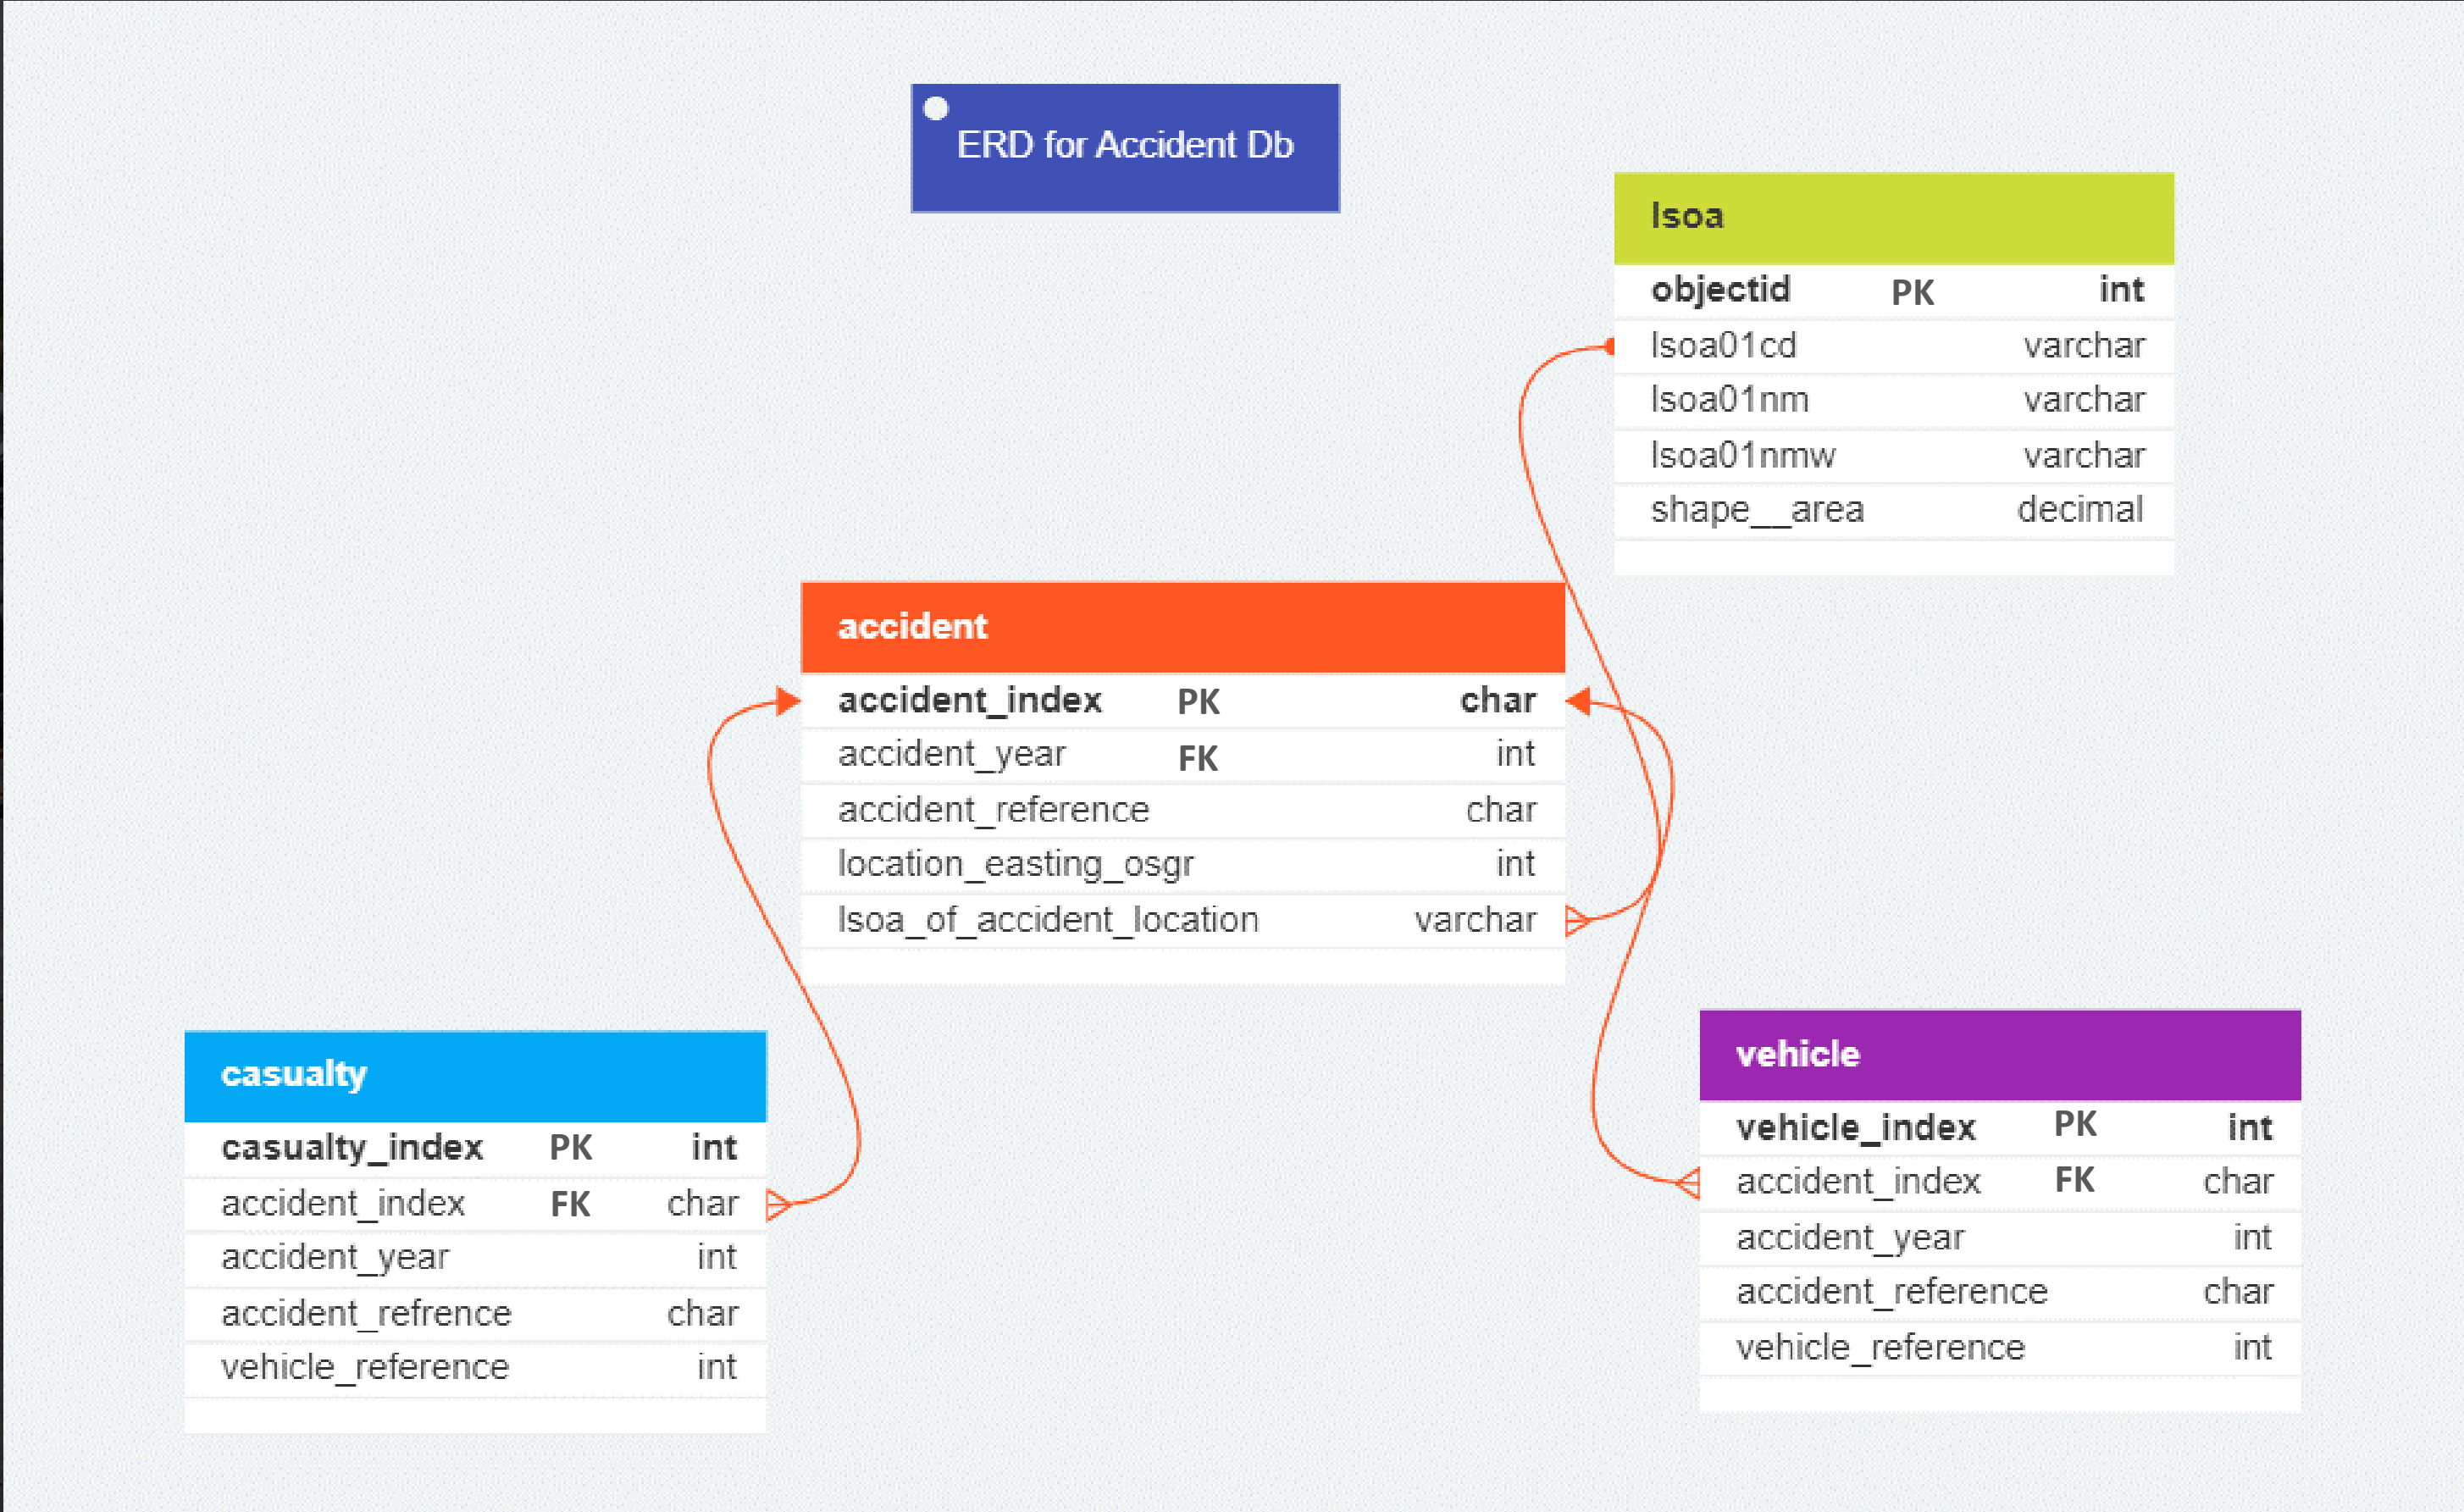

The Government may Implement the following solutions:

1. Implement security mechanisms using SQL
2. Improve scalability through SQL by horizontal scaling, and vertical scaling.
3. Extract audit logs and trails to track and record data access modifications
4. Implement and enforce data retention policies using SQL
5. Implement constraints referential integrity through primary and foreign key relationships, and the use of transactions.
6. Implement anonymization and Pseudonymization techniques with the SQL database

Entity Relationship Diagram

SQL Tutorials

Age of the oldest driver/rider in the casualty table

localhost:8888/notebooks/Downloads/Big%20Data%20and%20Data%20Mining%20-%20Presentation-Copy1.ipynb

jupyter Big Data and Data Mining - Presentation-Copy1 Last Checkpoint: an hour ago (unsaved changes) Logout

34377 34378 W01001896 Cardiff 020E Caerdydd 020E 3.124395e+05 3823.366435 c885f171-a56e-4e2b-8d09-1c7d6efedd67

34378 rows x 7 columns

To do SQL Commands:

A. The age of the oldest driver/rider in the casualty table

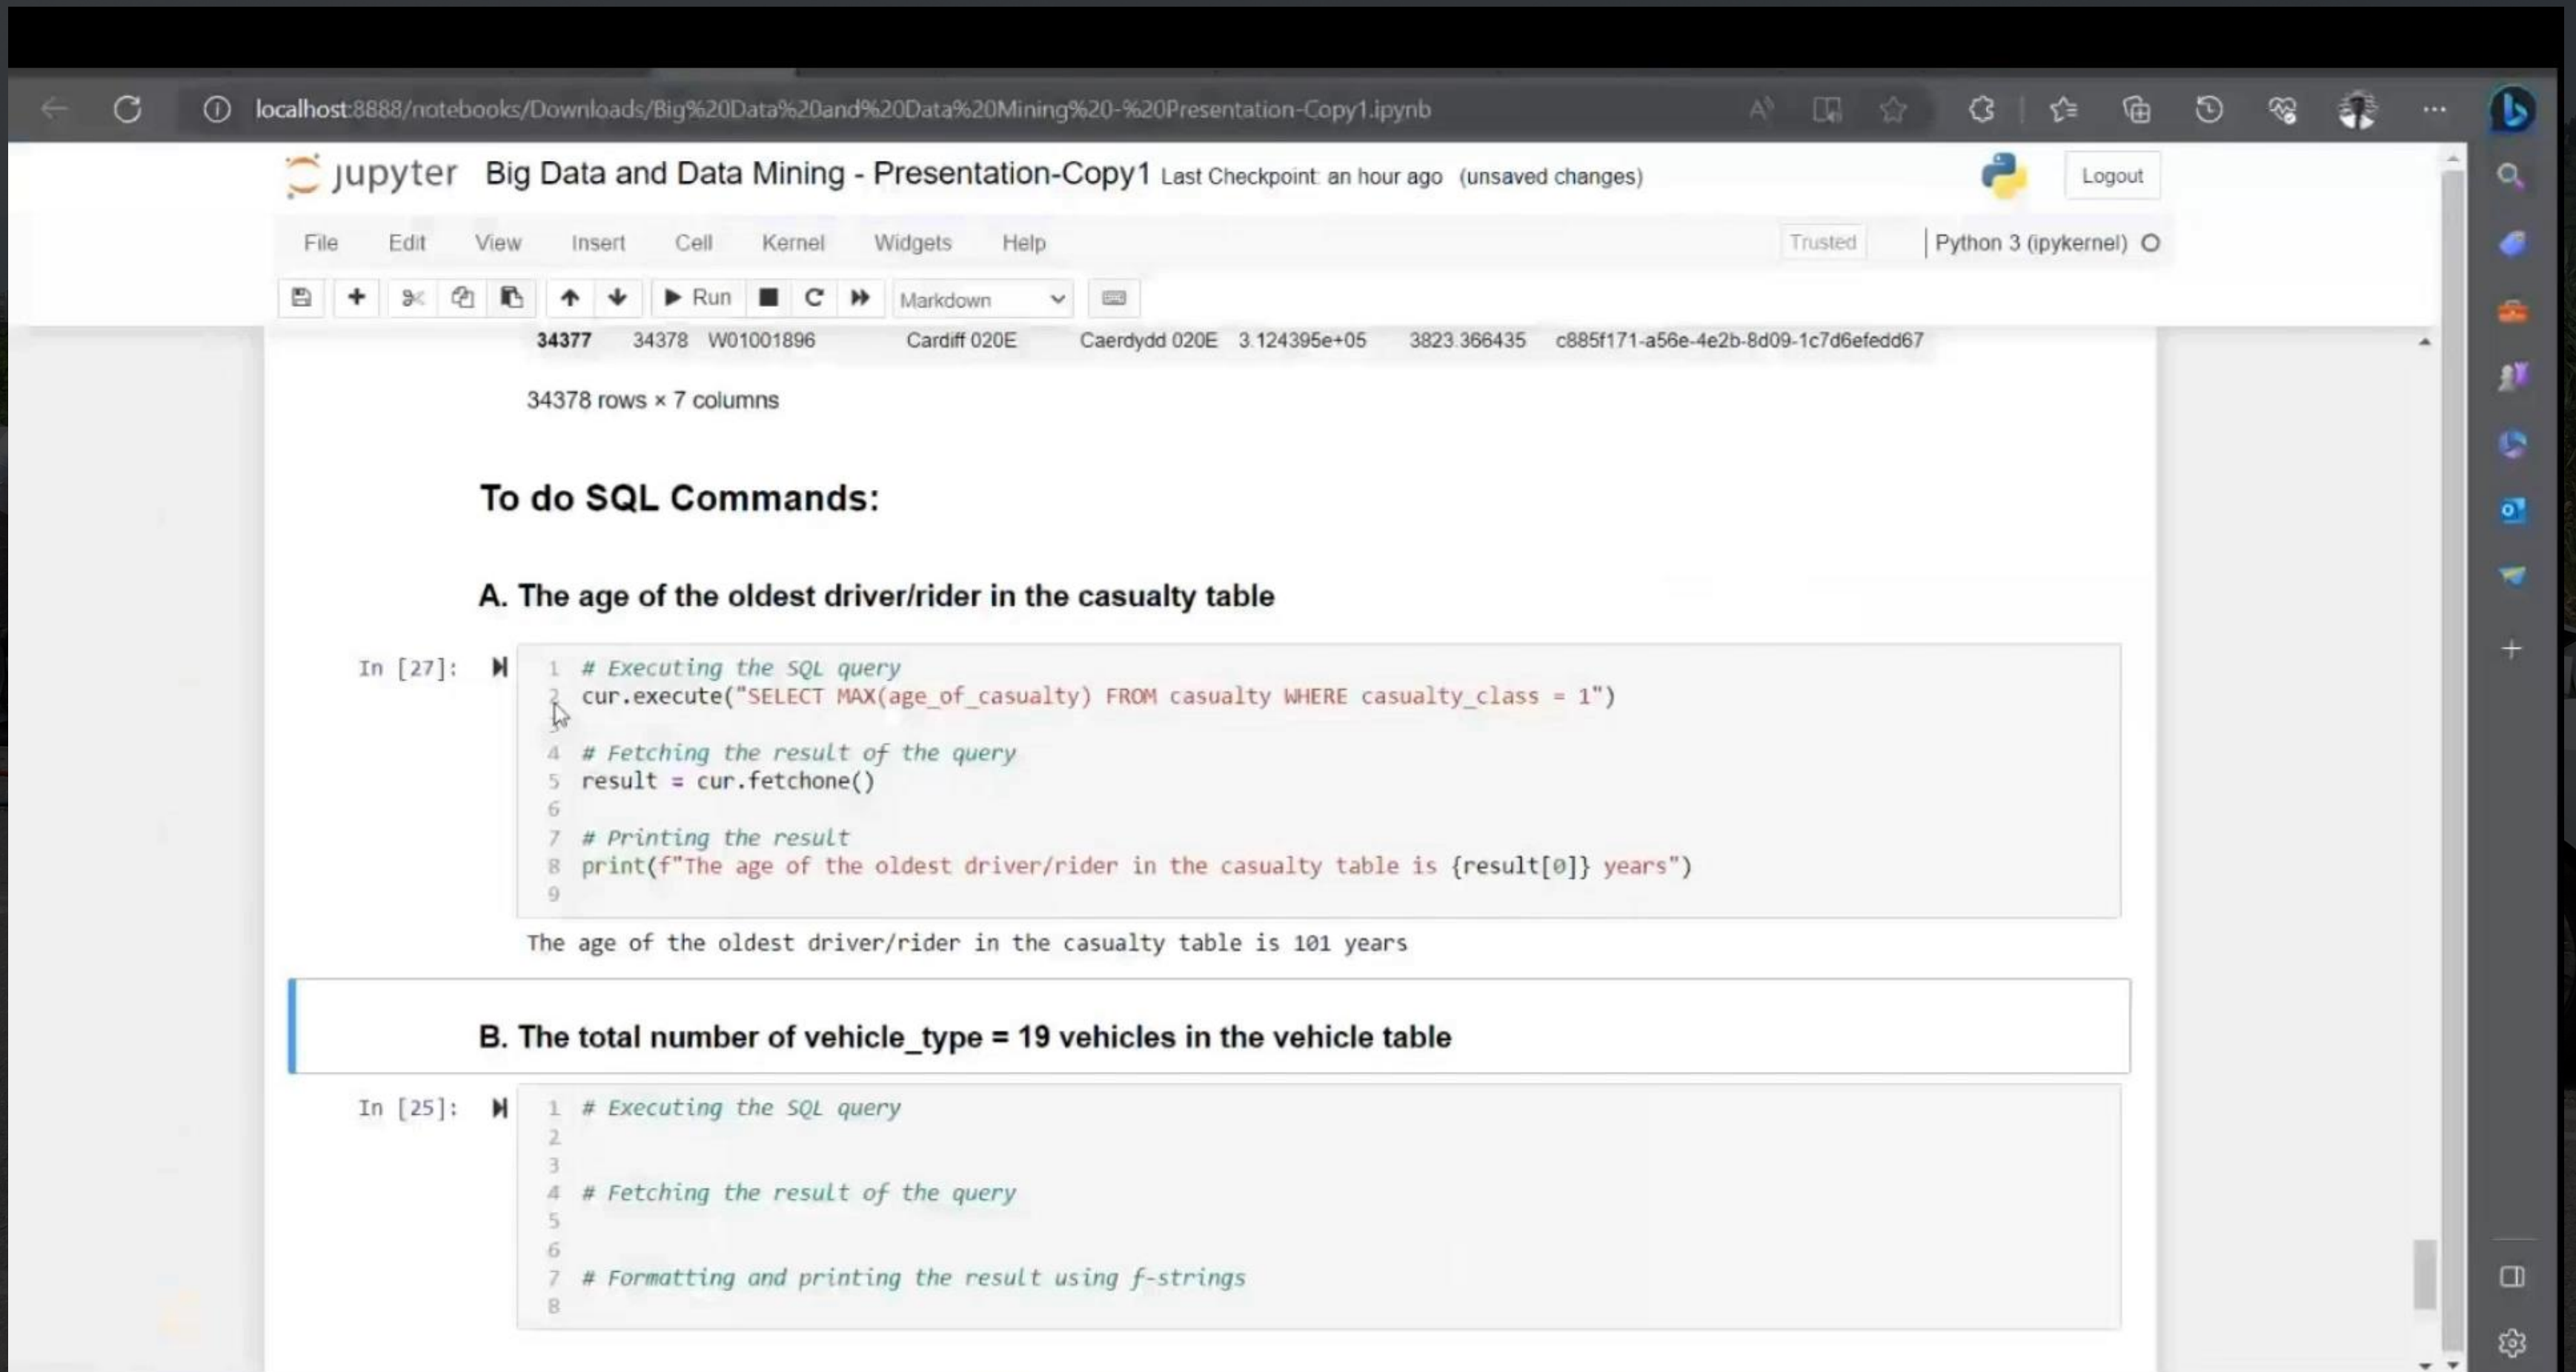

```
In [24]: 1 # Executing the SQL query
2
3
4 # Fetching the result of the query
5
6
7 # Printing the result
8
9
```

B. The total number of vehicle_type = 19 vehicles in the vehicle table

```
In [25]: 1 # Executing the SQL query
2
3
4 # Fetching the result of the query
5
6
7 # Formatting and printing the result using f-strings
8
```

C. The sex of driver, sex of casualty, speed limit and age of vehicle for accidents in all the lower layer super output area (LSOA) regions of Kingston Upon Hull

The Total number of vehicle type= 19 vehicles

The screenshot shows a Jupyter Notebook titled "Big Data and Data Mining - Presentation-Copy1" running on a local host. The notebook displays a table with 34378 rows and 7 columns. The table headers are: 34377, 34378, W01001896, Cardiff 020E, Caerdydd 020E, 3.124395e+05, 3823.366435, and c885f171-a56e-4e2b-8d09-1c7d6efedd67. Below the table, there are two sections for SQL commands:

To do SQL Commands:

A. The age of the oldest driver/rider in the casualty table

In [27]:

```
1 # Executing the SQL query
2 cur.execute("SELECT MAX(age_of_casualty) FROM casualty WHERE casualty_class = 1")
3
4 # Fetching the result of the query
5 result = cur.fetchone()
6
7 # Printing the result
8 print(f"The age of the oldest driver/rider in the casualty table is {result[0]} years")
9
```

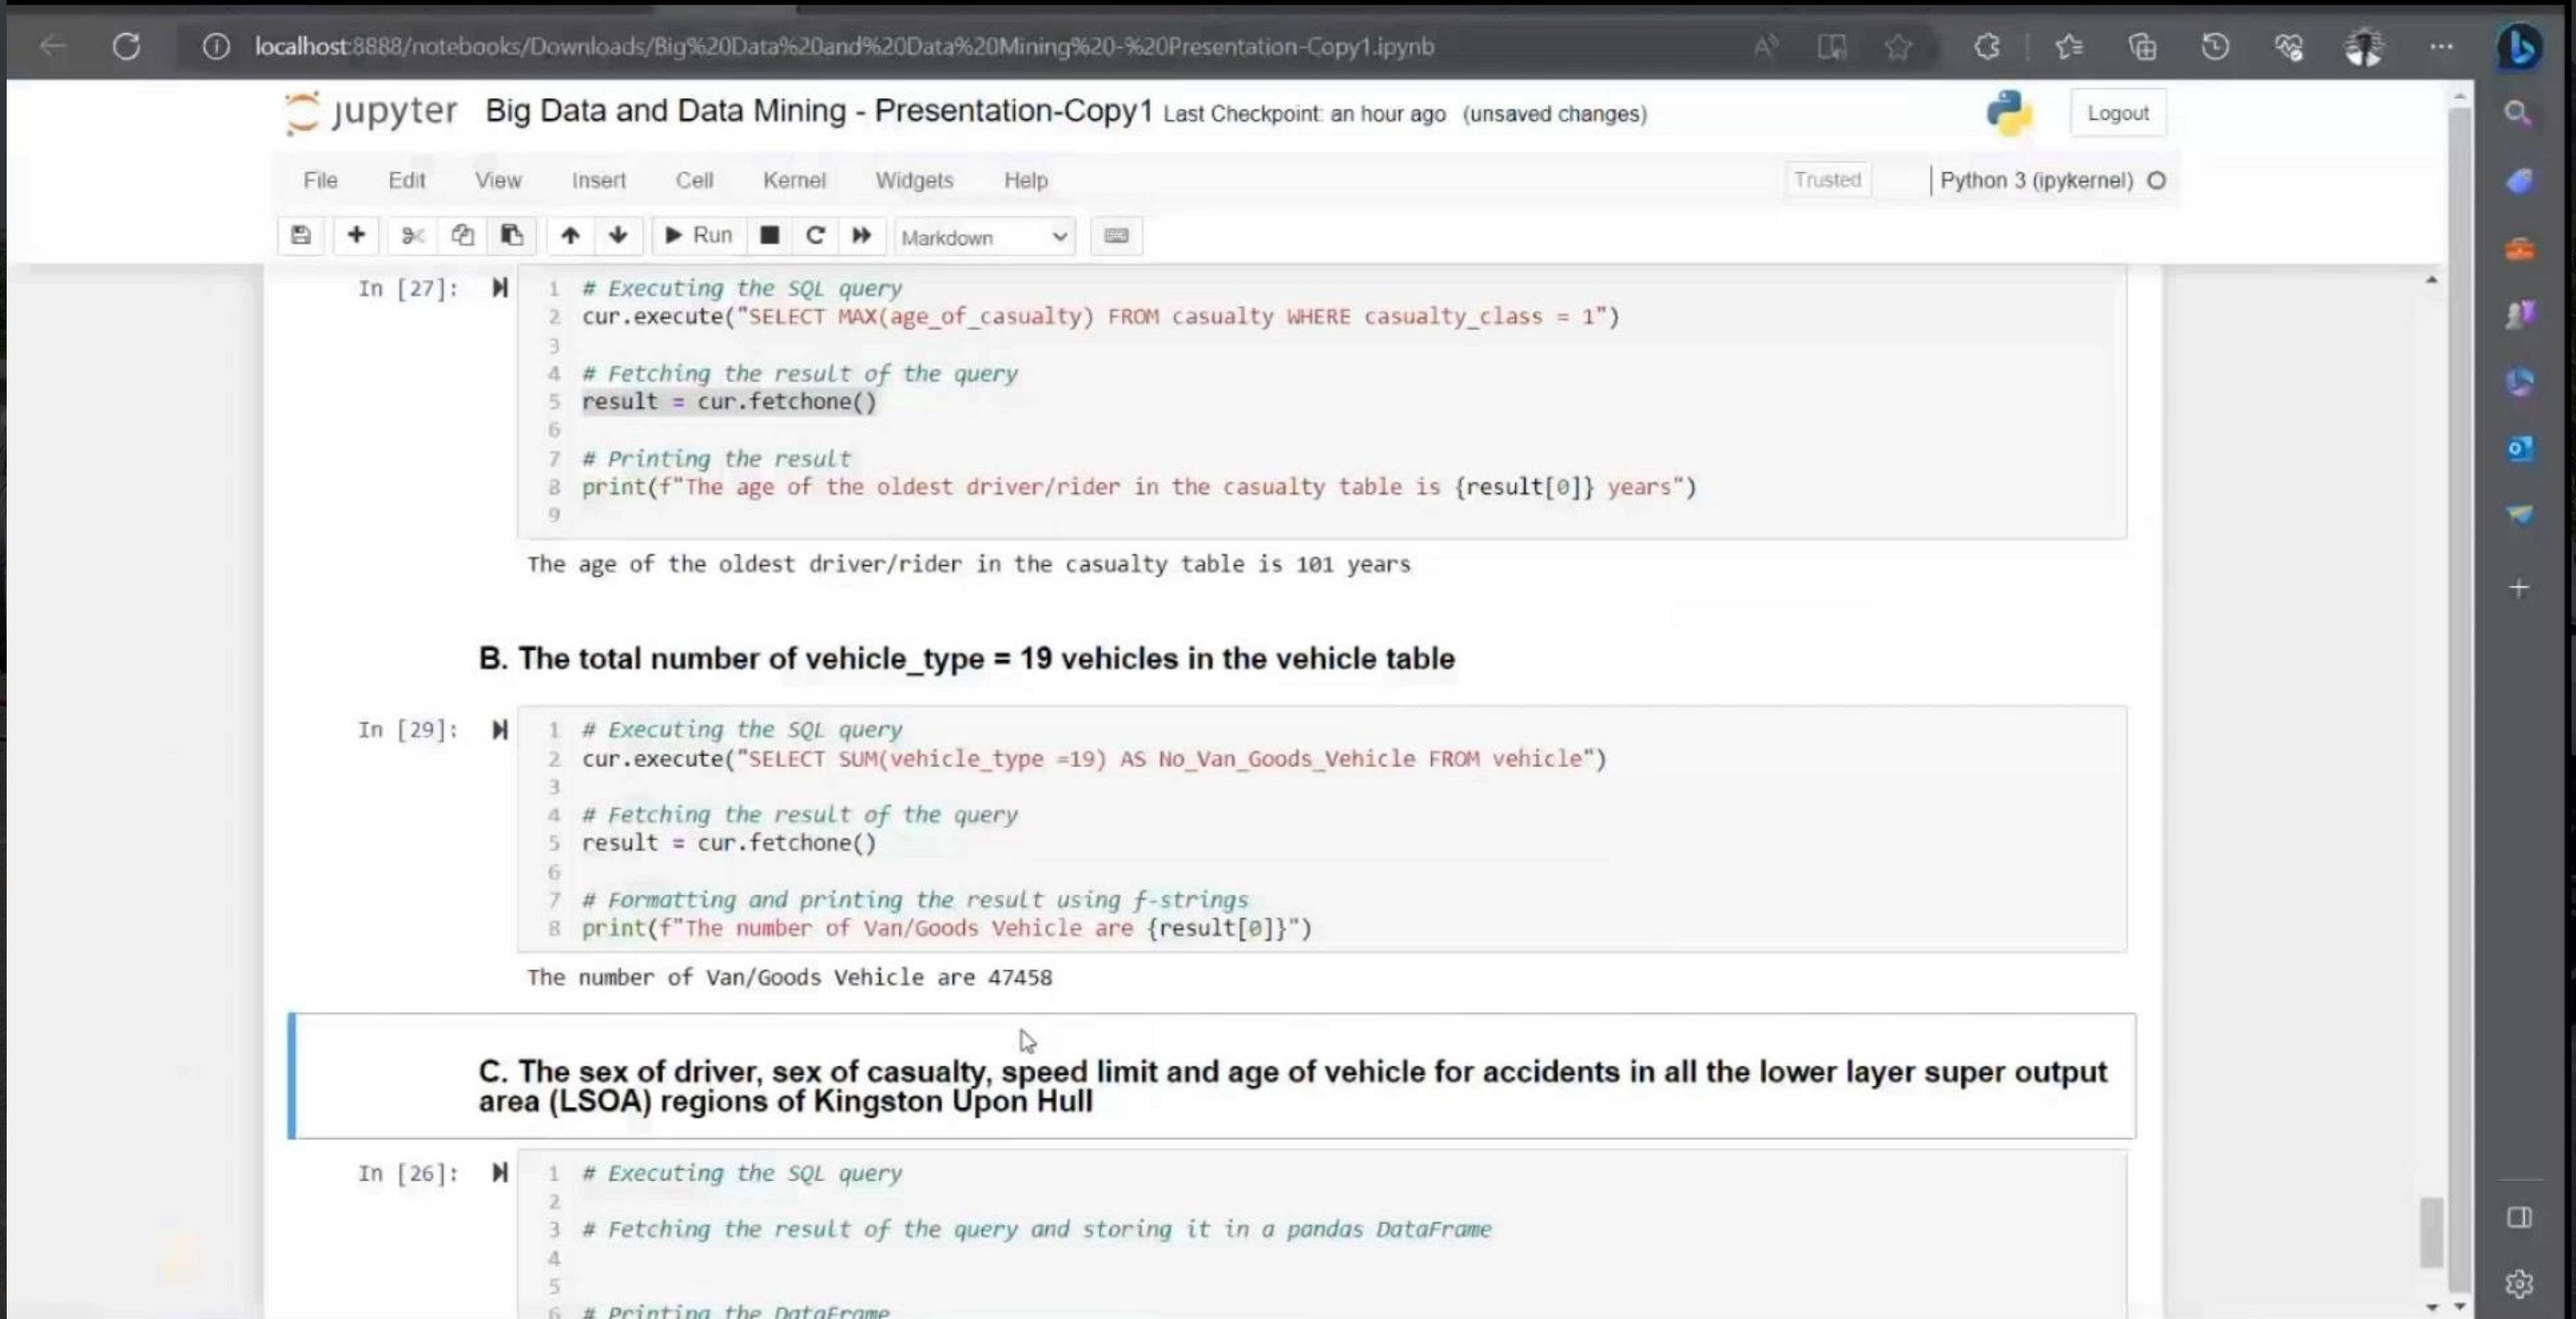

The age of the oldest driver/rider in the casualty table is 101 years

B. The total number of vehicle_type = 19 vehicles in the vehicle table

In [25]:

```
1 # Executing the SQL query
2
3
4 # Fetching the result of the query
5
6
7 # Formatting and printing the result using f-strings
8
```

The sex of driver, casualty, speed limit & age of vehicles in LSOA of Hull

The screenshot shows a Jupyter Notebook titled "Big Data and Data Mining - Presentation-Copy1" running on a local host. The notebook contains three code cells, each with a title and a corresponding SQL query. The first cell, labeled "In [27]:", executes a query to find the maximum age of a casualty where the casualty class is 1, resulting in the output "The age of the oldest driver/rider in the casualty table is 101 years". The second cell, labeled "In [29]:", executes a query to find the sum of vehicle types equal to 19, resulting in the output "The number of Van/Goods Vehicle are 47458". The third cell, labeled "In [26]:", is partially visible and shows the beginning of a query to fetch data for accidents in all the lower layer super output area (LSOA) regions of Kingston Upon Hull.

File Edit View Insert Cell Kernel Widgets Help Trusted Python 3 (ipykernel)

In [27]:

```
1 # Executing the SQL query
2 cur.execute("SELECT MAX(age_of_casualty) FROM casualty WHERE casualty_class = 1")
3
4 # Fetching the result of the query
5 result = cur.fetchone()
6
7 # Printing the result
8 print(f"The age of the oldest driver/rider in the casualty table is {result[0]} years")
9
```

The age of the oldest driver/rider in the casualty table is 101 years

B. The total number of vehicle_type = 19 vehicles in the vehicle table

In [29]:

```
1 # Executing the SQL query
2 cur.execute("SELECT SUM(vehicle_type =19) AS No_Van_Goods_Vehicle FROM vehicle")
3
4 # Fetching the result of the query
5 result = cur.fetchone()
6
7 # Formatting and printing the result using f-strings
8 print(f"The number of Van/Goods Vehicle are {result[0]}")
```

The number of Van/Goods Vehicle are 47458

C. The sex of driver, sex of casualty, speed limit and age of vehicle for accidents in all the lower layer super output area (LSOA) regions of Kingston Upon Hull

In [26]:

```
1 # Executing the SQL query
2
3 # Fetching the result of the query and storing it in a pandas DataFrame
4
5
6 # Printing the DataFrame
```
